Following pathways with isotopes

Stephen Barnes

University of Alabama at Birmingham

sbarnes@uab.edu

1

Synopsis

- Extra value in the M+2 isotope peak
- Using isotopes in tracing metabolic and physiologic pathways
 - Historical
 - Fluxomics
 - Physiology
- Isotopes and enhanced chemical detection of metabolites
- Disturbing energy levels in NMR

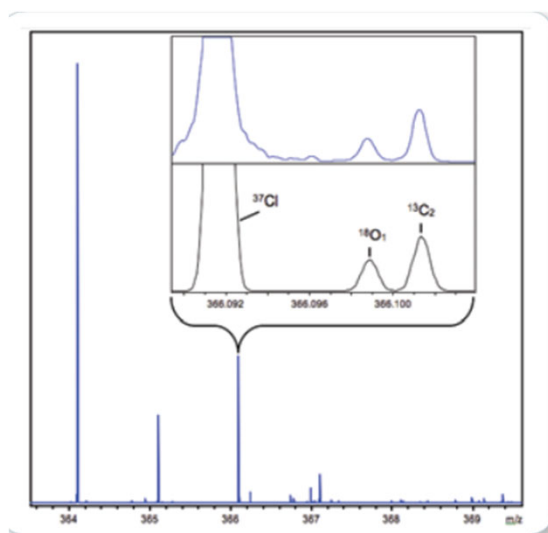

2

Value of natural isotopes

- The natural abundance of isotopes enables the investigator to determine the charge state of an ion
- The principal contribution to $[M+H]^+$ or $[M-H]^-$ isotope ions comes from ^{13}C (~1.1% of all carbon atoms)
- The intensity of the $[M+H]^+$ or $[M-H]^-$ ^{13}C isotope ion increases relative to the number of carbon atoms
- There is often an observable $^{13}\text{C}_2$ isotope peak

3

The importance of the M+2 ion

From Bruker

4

Value of the [M+2] peak

- The mass difference due to a nominal increase in mass of 2 contains a lot of information
 - These are isotopic mass differences for each of the common elements

• $^1\text{H}_2/{}^2\text{H}_2$	2 x 1.006277	= 2.012554 (0.012%)
• $^{12}\text{C}_2/{}^{13}\text{C}_2$	2 x 1.003355	= 2.006710 (1.078%)
• $^{14}\text{N}_2/{}^{15}\text{N}_2$	2 x 0.997035	= 1.994079 (0.364%)
• $^{16}\text{O}_2/{}^{17}\text{O}_2$	2 x 1.004217	= 2.008434 (0.038%)
• $^{16}\text{O}_2/{}^{18}\text{O}_1$	1 x 2.004246	= 2.004246 (0.205%)
• $^{32}\text{S}_2/{}^{33}\text{S}_2$	2 x 0.999387	= 1.998774 (0.752%)
• $^{32}\text{S}_2/{}^{34}\text{S}_1$	1 x 1.995796	= 1.995796 (4.252%)
 - Needs the highest possible mass resolution
 - FT-ICR

5

Using isotopes to trace a pathway

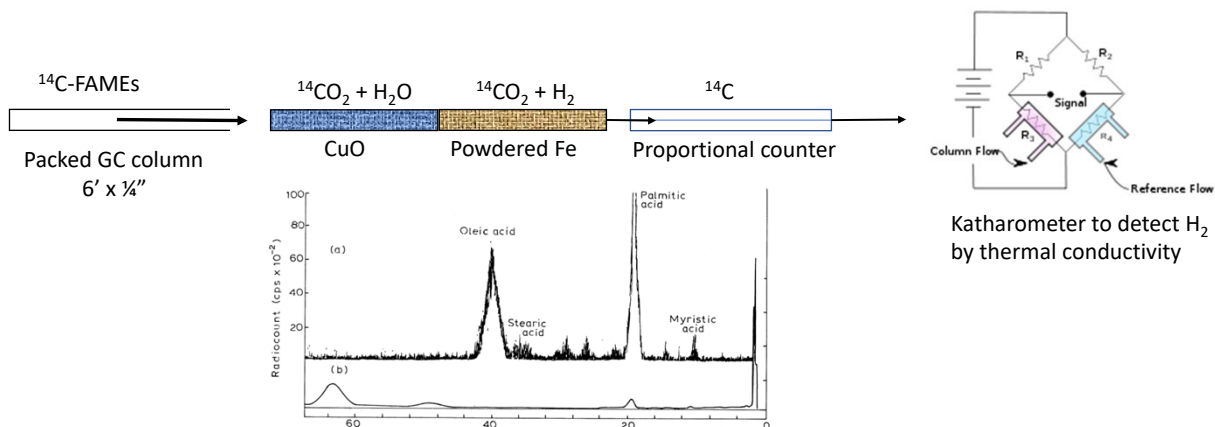

- Early studies (1930s) used ${}^2\text{H}$, ${}^{13}\text{C}$ and ${}^{15}\text{N}$ labeling to map pathways
 - Limited to 1-200 m/z mass range
- 1950s/60s ${}^{14}\text{C}$ -radiotracers
 - 2D-Paper or thin layer chromatography
 - Radio gas chromatography
 - labeling of specific carbon atoms

David Rittenberg

6

Radio-gas chromatography of FAMES In Tony James' lab

We were studying an isomer of palmitoleic acid – from β -oxidation of oleic acid, or direct desaturation?
Collected the 16:1 peak using a gas density balance (no degradation) in **ether-soaked cotton wool**.
Subjected to oxidation with permanganate-periodate – identified C_{11} monobasic acid and C_7 dibasic acid, i.e., 16:1 Δ^7

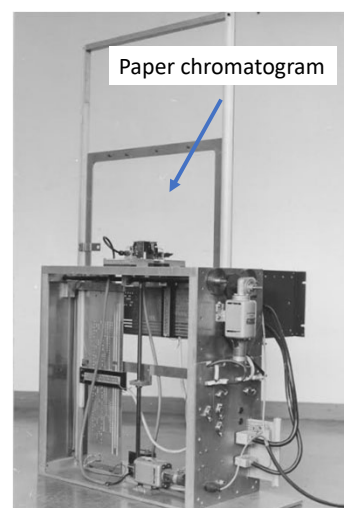

7

Early beginnings of metabolomics in London

- Sir Ernst Chain (1945 Nobel Laureate – the biochemist who characterized penicillin)
 - Also renowned for his work on microanalysis
- Used 2D-paper chromatography to resolve glycolytic, Krebs cycle and amino acids derived from ^{14}C -glucose
 - Geiger counter mounted on a typewriter frame
 - Digitized the collected data and prepared computer-generated figures

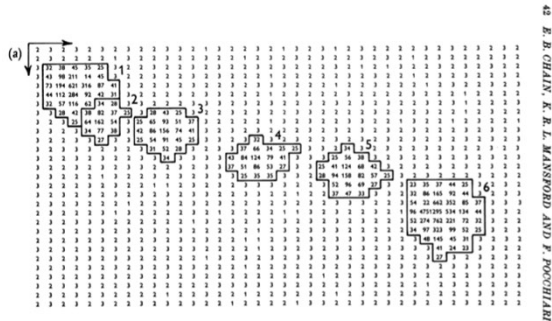

Keith Mansford

Stream splitter for radio GC

S. Barnes, PhD Thesis

12

Popjak scintillation cell

The key to this device was the mixing generated by the gas from the GC column causing (scintillation) fluid (toluene) to flow out of the bottom of the scintillation chamber, both to aid recirculation and to provide a source of solvent vapors that more efficiently extracted the compounds in the gas phase.

13

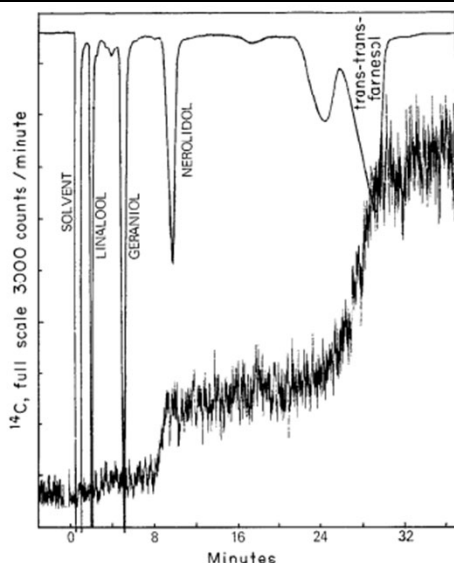

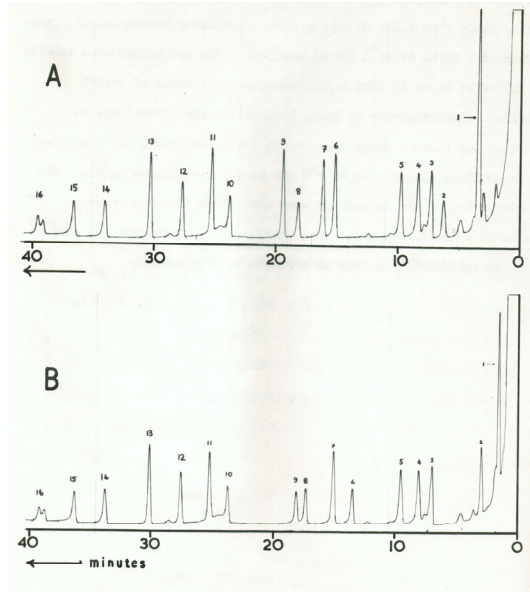

FIG. 19. Gas-liquid radiochromatogram of F_1 (cf. Fig. 4) from the chromatography on DEAE-cellulose of the butanol extract of an incubation of liver microsomes with farnesyl pyrophosphate. Nearly 30% of the total radioactivity in the specimen was accounted for by ^{14}C in nerolidol. Cochromatography with added markers of linalool, geraniol, nerolidol, *cis-trans*- and *trans-trans*-farnesol; simultaneous recording of mass and radioactivity detector.

Application to the discovery of a new intermediate in squalene biosynthesis

It's worth reading this 1969 article in J Biol Chem for the depth of analysis that was undertaken to prove the identity of this intermediate

29

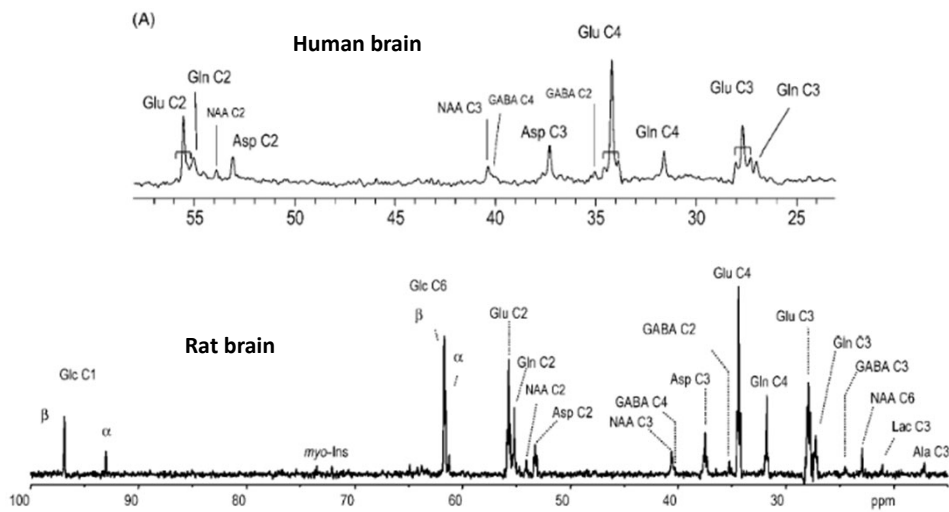

30

Biological NMR

- If ^{13}C -labeled precursors are used, there is a very much enhanced set of ^{13}C NMR resonances
- You have a choice between analysis of a biological extract (have all the time you need)
- And direct analysis in tissue:
 - Surface coil technology in the living animal
 - Magic Angle Spinning on a piece of tissue

31

NMR analysis of metabolites from ^{13}C -labeled precursors using pulse sequences

32

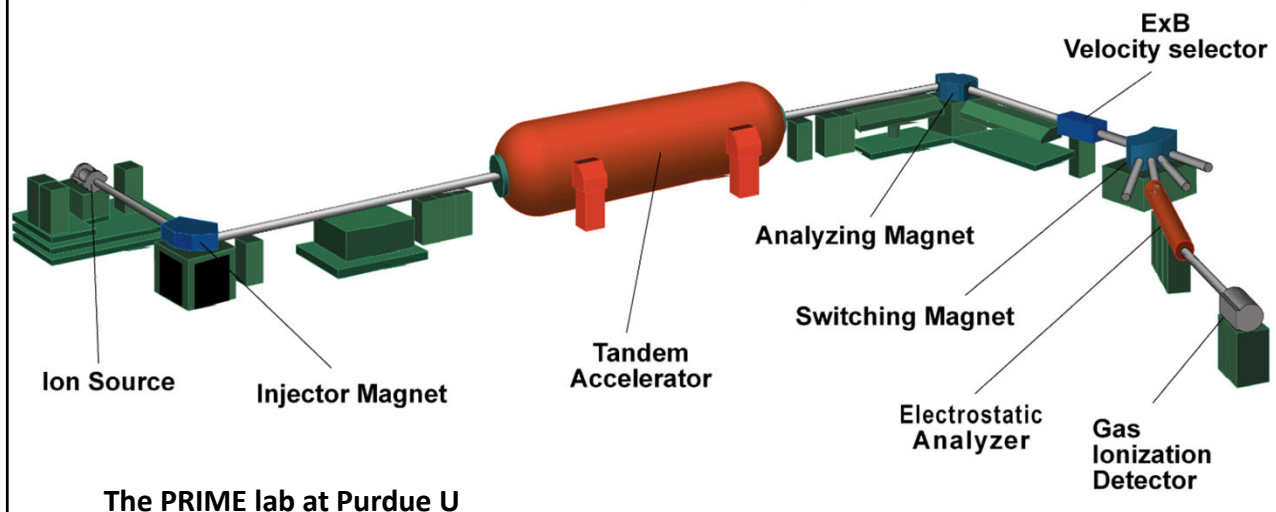

Probing the depths of metabolite penetration into tissues

Ultimate sensitivity by sacrificing metabolite identity at physiologic sites by ^{14}C -labeling the precursor of interest

Technology the same as the one used for radiocarbon dating

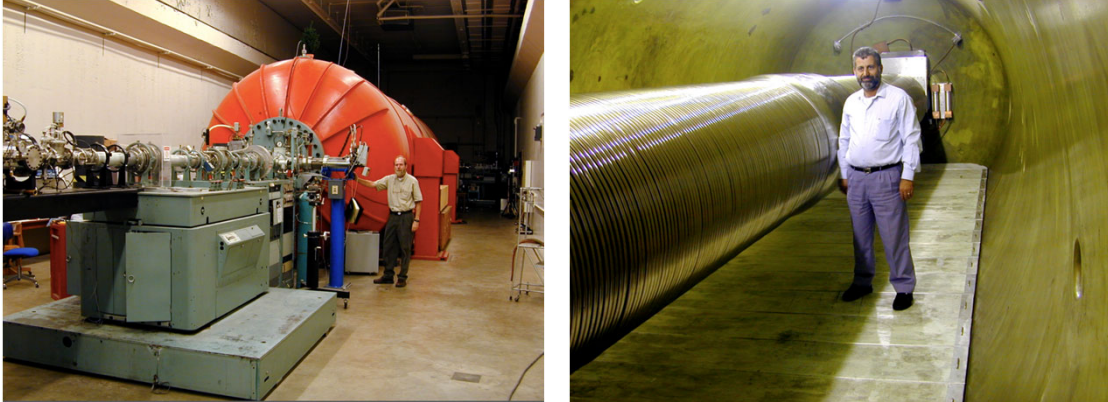

33

Accelerator mass spectrometry (AMS) The ultimate mass spectrometer

48

Hyperpolarized NMR

- **NMR's advantages**
 - Non-destructive
 - Quantitative
 - Usable *in situ*
- **NMR's disadvantages**
 - The difference in the populations of the low and high energy states is 1 part in a million, i.e., low sensitivity
 - If an excess in the high energy state could be achieved, NMR could become >10,000 times more sensitive, albeit that the half-life in the hyperpolarized state may be only 30 s

50

Making hyperpolarized dihydroxyacetone

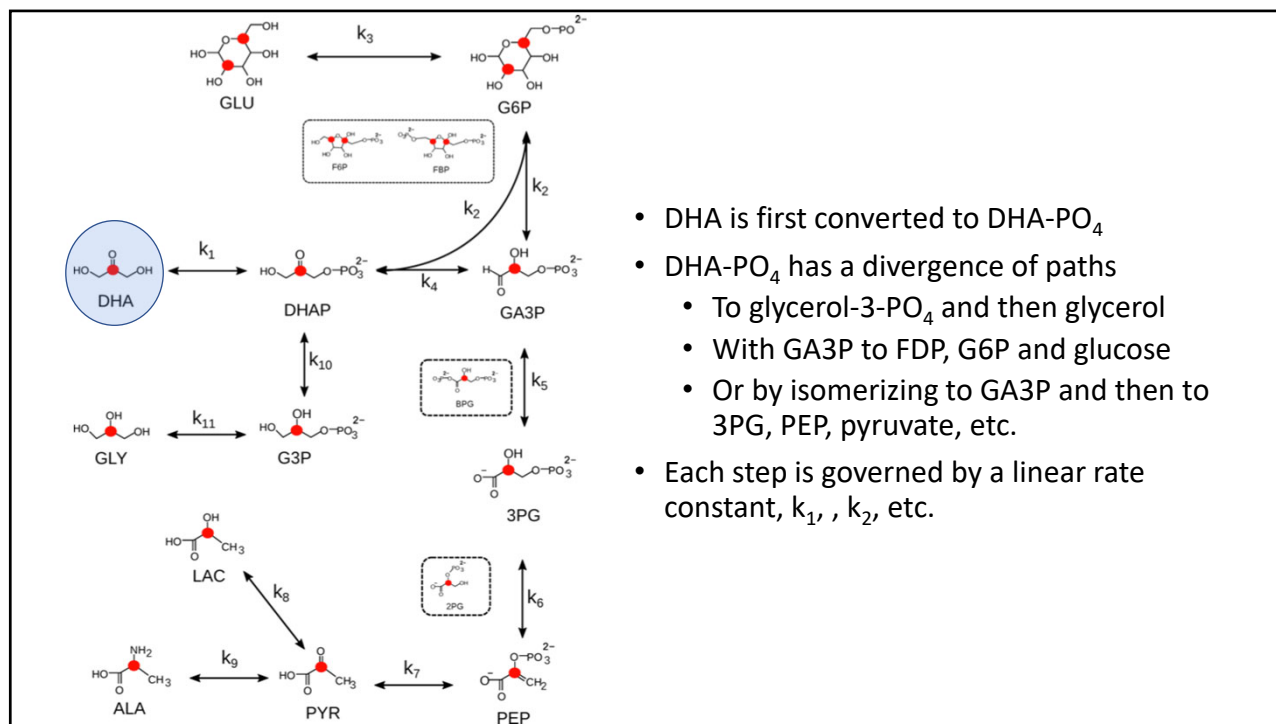

- An 8.0 M solution of [2-¹³C]DHA in a (2:1) water:dimethyl sulfoxide (DMSO) mixture was doped with 15 mM stable trityl free radical (Oxford Instruments Molecular Biotools) and 1.0 mM ProHance.
- The frozen sample was cooled to **1.05 K** in a pumped helium bath inside the magnetic field (3.35 T) of the HyperSense, and the microwave irradiation was turned on.
- Polarization took 1.5–2 h, the irradiation was turned off, and the sample was rapidly dissolved with 4 ml of hot (190 °C) PBS (10 mM, pH 7.4) and transferred to an 89-mm vertical 9.4 T NMR spectrometer for transfer into the perfusate chamber and spectral acquisition.

51

Animal experiment and data collection

- Isolated perfused mouse liver placed inside the wide bore of the NMR
- Liver perfused with either 0.2 mM octanoate or 0.2 mM octanoate/2 mM pyruvate
- Hyperpolarized DHA added and first free induction decay collected within 1 msec
- Subsequent FID collection was for 1 sec with a 2 sec delay before the next acquisition – 3 sec cycle time
- Total number of collections = 60, i.e., a total of 3 min
- Half-life of the ¹³C signal was 32 sec, i.e., by 3 min the signal was 1.5625% of the starting signal

Production of highly concentrated and hyperpolarized metabolites within seconds in high and low magnetic fields†

Sergey Korchak,^{ab} Meike Emondts,^{cd} Salvatore Mamone,^{ab} Bernhard Blümich^{bd} and Stefan Glöggler^{bd}

Hyperpolarized metabolites are very attractive contrast agents for *in vivo* magnetic resonance imaging studies enabling early diagnosis of cancer, for example. Real-time production of concentrated solutions of metabolites is a desired goal that will enable new applications such as the continuous investigation of metabolic changes. To this end, we are introducing two NMR experiments that allow us to deliver high levels of polarization at high concentrations (50 mM) of an acetate precursor (55% ¹³C polarization) and acetate (17% ¹³C polarization) utilizing 83% *para*-state enriched hydrogen within seconds at high magnetic field (7 T). Furthermore, we have translated these experiments to a portable low-field spectrometer with a permanent magnet operating at 1 T. The presented developments pave the way for a rapid and affordable production of hyperpolarized metabolites that can be implemented in e.g. metabolomics labs and for medical diagnosis.
